CPU Pipelining Issues

What have you been beating your head against?

This pipe stuff makes my head hurt!

Finishing up Chapter 4
Structural Data Hazard

Consider LOADS:
Can we fix this problem using bypass paths like before?

For a `lw` instruction fetched during clock `i`, data isn’t returned from memory until late into cycle `i+3`. Bypassing will fix `xor` but not `add`!

Load data hazards are complicated by the fact that their result is resolved later than the ALU pipeline stage.

Source operands that reference the destination of a previous `lw` instruction.
Load Delays

Bypassing CAN'T fix the problem with add since the data simply isn't available! In order to fix it we have to add pipeline interlock hardware to stall the add's execution, or else program around it.

```
lw $t4,0($t1)
add $t5,$t1,$t4
xor $t6,$t3,$t4
```

Adding stalls to the pipeline in order to assure proper operation is sometimes called inserting pipeline BUBBLES.

<table>
<thead>
<tr>
<th></th>
<th>i</th>
<th>i+1</th>
<th>i+2</th>
<th>i+3</th>
<th>i+4</th>
<th>i+5</th>
<th>i+6</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF</td>
<td>lw</td>
<td>add</td>
<td>xor</td>
<td>xor</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RF</td>
<td>lw</td>
<td>add</td>
<td>add</td>
<td>xor</td>

<td></td>
<td></td>
</tr>
<tr>
<td>ALU</td>
<td>lw</td>
<td>nop</td>
<td>add</td>
<td>xor</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>WB</td>
<td>lw</td>
<td>nop</td>
<td>add</td>
<td>xor</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This requires inserting a MUX just before the instruction register of the ALU stage, IR^ALU, to annul the add (by inserting a NOP) as well as, clock enables on the PC and IR pipeline registers of earlier pipeline stages to stall the execution without annuling any instructions. This is how the simulator, SPIM works.
Punting on Load Interlock

Early versions of MIPS did not include a pipeline interlock, thus, requiring the compiler/programmer to work around it.

If compiler knows about load delay, it can often rearrange the code sequence to eliminate the hazard. Many compilers can provide implementation-specific instruction scheduling. This requires no additional H/W, but it leads to awkward instruction semantics. We’ll include interlocks in miniMIPS.

\[
\begin{array}{ccccccc}
  & i & i+1 & i+2 & i+3 & i+4 & i+5 & i+6 \\
  \text{IF} & \text{lw} & \text{nop} & \text{add} & \text{xor} & \text{} & \text{} & \text{} \\
  \text{RF} & \text{lw} & \text{nop} & \text{add} & \text{xor} & \text{} & \text{} & \text{} \\
  \text{ALU} & \text{lw} & \text{nop} & \text{add} & \text{xor} & \text{} & \text{} & \text{} \\
  \text{WB} & \text{lw} & \text{nop} & \text{add} & \text{xor} & \text{} & \text{} & \text{} \\
\end{array}
\]

\[
\text{lw} \quad \text{t4},0(\text{t1}) \\
\text{nop} \\
\text{add} \quad \text{t5},\text{t1},\text{t4} \\
\text{xor} \quad \text{t6},\text{t3},\text{t4}
\]
Load Delays (cont’d)

But, but, what about FASTER processors?

FACT: Processors have been become very fast relative to memories!

Can we just stall the pipe longer? Add more NOPs?

ALTERNATIVE: Longer pipelines.

1. Add “MEMORY WAIT” stages between INITIATION of load operation and when it returns data.

2. Build pipelined memories, so that multiple (say, N) memory transactions can be in progress at once.

3. (Optional). Stall pipeline when the N limit is exceeded.

4-Stage pipeline requires READ access in LESS than one clock.

SOLUTION: A 5-Stage pipeline that allows nearly two clocks for data memory accesses...
5-Stage miniMIPS

- Omits some details
- NO bypass or interlock logic

Address is available right after instruction enters Memory stage

almost 2 clock cycles

Data is needed just before rising clock edge at end of Write Back stage
One More Fly in the Ointment

There is one more structural hazard that we have not discussed. That is, the saving, and subsequent accesses, of the return address resulting from the jump-and-link, jal, instruction.

Moreover, given that we have bought into a single delay slot, which is always executed, we now need to store the address of the instruction **FOLLOWING** the delay slot instruction.

We need to return here, to PC+8, not PC+4. Once more we need to rewrite the ISA spec!

```
jal   sqr  # call procedure
addi  $a0,$0,10  # set arg in delay slot
addi  $t0,$v0,-1  # return address
```
Return Address Register Writes

# The code: Assume Reg[LP] = 100...
    add $ra,$0,$0
    jal f
    addi $ra,$ra,4  # In delay slot

    ... 
    f: xor $t0,$ra,$0
    or  $r1,$0,$ra
    add $t2,$0,$ra

Can we make the regfile accesses of the 3 instructions following the jal work by bypassing?

Where do we get the right return address from?
JAL PC Bypasses

On JALs, the register file saves the next address from the DELAY SLOT instruction (often PC+8).

Note this bypass is routed from the PC pipeline not from the ALU output. Thus, we need to add bypass paths for PC\textsubscript{MEM}.

addi $31,$31,4
jal f
add $ra,$0,$0

(fetching xor at f)
JAL PC Bypasses

(fetching or at f+4)

We need another PC\textsuperscript{ALU} bypass.

In this case, the bypass path supplies the $31$ operand for the XOR instruction.

xor $8, $31, $0

addi $31, $31, 4

jal f

add $ra, $0, $0

Comp 411 – Spring 2012
JAL PC Bypasses

And, we need another PC\textsuperscript{MEM} bypass.

In this case, the bypass path supplies the $31 operand for the OR instruction.

PC\textsuperscript{WB} is already taken care of, for the following ADD, using the WB stage bypass at the output of the WDSEL mux.
5-Stage miniMIPS

We wanted a simple, clean pipeline but...

• broke the sequential semantics of ISA by adding a branch delay-slot and early branch resolution logic
• added A/B bypass muxes to get data before it’s written to regfile
• added CLK EN to freeze IF/RF stages so we can wait for lw to reach WB stage
Bypass MUX Details

The previous diagram was oversimplified. Really need for the bypass muxes to precede the A and B muxes to provide the correct values for the jump target (JT), write data, and early branch decision logic.
Bypass Logic

miniMIPS bypass logic (need two copies for A/B data):

* If instruction is a sw (doesn’t write into regfile), set rt for ALU/MEM/WB to $0
• Added branch delay slot and early branch resolution logic to fix a CONTROL hazard

• Added lots of bypass paths and detection logic to fix various STRUCTURAL hazards

• Added pipeline interlocks to fix load delay STRUCTURAL hazard

Comp 411 – Spring 2012

4/2/12
Pipeline Summary (I)

• Started with unpipelined implementation
  - direct execute, 1 cycle/instruction
  - it had a long cycle time: mem + regs + alu + mem + wb

• We ended up with a 5-stage pipelined implementation
  - increase throughput (3x???)
  - delayed branch decision (1 cycle)
    Chose to execute instruction after branch
  - delayed register writeback (3 cycles)
    Add bypass paths (6 x 2 = 12) to forward correct values
  - memory data available only in WB stage
    Introduce NOPs at IR\text{ALU}, to stall IF and RF stages
    until LD result was ready
Pipeline Summary (II)

Fallacy #1: Pipelining is easy
Smart people get it wrong all of the time! Costs? Re-spins of the design. Force S/W folks to devise program/compiler workarounds.

Fallacy #2: Pipelining is independent of ISA
Many ISA decisions impact how easy/costly it is to implement pipelining (i.e. branch semantics, addressing modes). Bad decisions impact future implementations. (delay slot vs. annul?, load interlocks?) and break otherwise clean semantics. For performance, S/W must be aware!

Fallacy #3: Increasing Pipeline stages improves performance
RISC = Simplicity???

“The P.T. Barnum World’s Tallest Dwarf Competition”
